Abstract

Conventional processes used to treat water and wastewater mainly removes the suspended solids, pathogens and biodegradable organic matter. The majority of persistent organic pollutants are not generally removed by these processes.

Persistent organic pollutants (POPs) constitute a class of anthropogenic substances (man-made) and can be found as trace quantity elsewhere in environment. They are toxic and bio-accumulate in humans, plants, animals, and have significant adverse impacts on human health and the environment, even at very low concentrations. They may cause cancer and disorders in the reproductive and immune systems as well as affecting the human developmental process. POPs do not readily break down in the environment with half-lives in soils in the order of years, although they may be transformed both physically and chemically over long periods of time. They exist in agricultural runoff, drainage to the sewerage system and industrial discharge.

In this study, three organic pollutants were selected for investigation humic acid as natural organic matter (NOM), metsulfuron methyl herbicide as POP, and biological treated sewage effluent (BTSE).

In the first part of the study, removal of humic substance representing NOM was investigated with various types of photocatalytic reactors. The percentage of dissolved organic carbon (DOC) removal with a batch reactor with titanium dioxide (TiO_2) as the photocatalyst ranged from 20 to 60 %. When powdered activated carbon (PAC) was added together with TiO_2 in the photo reactor, an improvement of more than twice DOC removal was noticed compared with the same amount of TiO_2 used alone. From these

results, the use of PAC - TiO₂ demonstrated superior removal of humic substance within a shorter contact time and higher removal efficiencies compared with using TiO₂ alone. Solid phase micro extraction coupled with Gas Chromatography and Flame ionisation detector (SPME/GC FID) equipped with DB-5 column was used to investigate the intermediate photo products during the photo-catalytic reaction. The manner in which intermediate photoproducts evolve and transform was demonstrated by the GC FID peak. The photo reaction can be summarised in the following way. The photo resistant by-products was adsorbed on the PAC-TiO₂ surface as shown in GC peak results. From DOC measurements, it is estimated that less than 25 % of the initial material remained. It is noted that during the PAC-TiO₂ batch process humic substance was removed immediately without forming a large amount of intermediate macro-molecules of humic substance.

In the photocatalysis continuous reactor, the humic substance removal efficiency was studied at different detention time (different flowrates). Better results were achieved at longer detention times as there was more contact time. When the PAC was added, the results also indicate that the photo-catalytic adsorption hybrid system removed a significant amount of humic substance (80% DOC removal) within a shorter contact time compared with using TiO₂ alone.

In a recirculated continuous plug flow reactors the factors for controlling removal rates in heterogeneous catalysis are mass transfer and surface reaction controls. These factors were improved when a high recirculation flow rate of 250 mL/min was used where flow is turbulent. When a small amount of PAC was added in addition to TiO₂, DOC removal improved to 80% in a shorter operation time of less than 10 minutes. The results with

various types of reactors indicate that recirculated continuous reactor gave the highest efficiency for removal of NOM (humic substance) in a shorter detention time.

In the second part of the study, the removal efficiency of metsulfuron methyl representing persistent organic pollutants (POPs) was studied. Batch reactor experiments conducted with different doses of TiO_2 and a small amount of PAC of 0.05 g/L revealed that the TOC removal efficiency can be significantly increased up to 80%. Further, the concentration profile and the rate constant showed superior photocatalysis performance in the presence of PAC. The PAC added during the photo-oxidation absorbed the intermediate compounds and thereby promoted the photocatalytic oxidation. The photooxidation with a detention time of 0.5 to 2 hours resulted in intermediate products of smaller molecular weight substances. In this study, a detailed analysis with SPME/GC (solid phase micro extraction/gas chromatography) was made to study on the photo oxidation intermediates. Following 10 min of residence time in the batch reactor the MM partitioned to smaller molecular weight compounds (or substrate) which occurred at different peak times during the GC (12.10, 14.25, 17.40, 19.63 and 20.18 minutes). After 5 hours of residence time in batch reactor, same substrate was found to be degraded. The photo oxidation was faster when activated carbon was used together with TiO_2 . The substrate that occurred at the peak times of 19.96 and 18.32 minutes during the GC had nearly disappeared, while the peak at time 14.27 minutes was lower. Some anionic by - photoproducts was investigated by using ion-chromatography. Nitrate and nitrite ions were formed as by-photoproducts. The formation of NO_3^- and NO_2^- anions occurred was faster when PAC was added to the photo-oxidation. Similarly, SO_4^{2-} ions form during the photo-oxidation of MM. Where PAC is present in the reactor, the concentration of SO_4^{2-} ions peaked earlier at approximately 50 min and thereafter reduces

its (SO_4^{2-}) concentration. The reduction in concentration of SO_4^{2-} after 50 min may be due to a portion being adsorbed on the PAC-TiO₂ surface and a portion being transformed to SO₂. In this study, the increase in efficiency of MM degradation is similarly attributed to the adsorption of photo-products on the more surface available with TiO₂ coupled with the PAC and active sites available to react with the pollutants. This reduces the competitive adsorption on active sites of PAC-TiO₂ increasing efficiency of degradation of MM. However, complicated photo-oxidation and by-products occur during these processes, and it is difficult to determine the actual mechanism of photo-catalytic reaction on the PAC-TiO₂ surface and the role of active sites because sophisticated instruments are required to do this. Experiments with recirculated continuous reactor were also conducted by using TiO₂ and TiO₂-PAC. The coupling of PAC with continuous heterogeneous TiO₂ photocatalysis leads to a faster degradation of MM than the heterogeneous TiO₂ photocatalysis alone. The incorporation of a small amount of PAC of 0.05 g/L with 1.5 g/L of TiO₂ led to 78% removal even with a short residence time of 5.25 minutes.

The granular activated carbon (GAC) filter was found to be very effective as a pre-treatment for the removal of herbicide (MM). Fixed bed column experiments packed with GAC were conducted with different GAC bed heights (5, 10 and 15 cm) and different effluent velocities. The GAC photocatalytic hybrid system showed upto 90% removal with GAC bed depth of 10 and 15 cm. The 10 and 15 cm deep GAC columns showed a steady state of effluent concentration. The retention time of GAC followed by photoreaction was less than 10 minutes.

Recirculated photocatalytic batch reactor experiments conducted with the biological

treated sewage effluent showed effective DOC removal. After start up, with the recirculated flow of 60 mL/min the effluent DOC was reduced by 60% in a period of 180 min, and became relatively stable. There were no large differences between results obtained with various recirculation flow rates. About 70 to 75 % DOC removal was achieved using flow rates of 100 mL/min and 250 mL/min. However, with a recirculation flow of 250 mL/min, DOC removal decreased to 65% down from the 73% DOC removal obtained with that of 100 mL/min rate. This can be explained in terms of the characteristics of the plug flow reactor. The flow rates used in this study were large enough to keep the catalyst in suspension, and to promote good mass transfer between the reactants. When a small amount of PAC (0.05g/L) was added, a complete removal of DOC was observed after 250 and 300 min operation times. The addition of 0.05 g/L of PAC adsorbent to the recirculated continuous reactor facilitated better organic removal than titania photocatalyst alone. DOC removal was further increased to 75% within 30 min of operation.

The membrane photocatalysis hybrid system was used to separate catalyst from the effluent. The membrane flux was very low and fouling was high when TiO_2 was tried to be filtered through MF filter. To facilitate TiO_2 separation, (i) pH adjustment and (ii) flocculation of TiO_2 slurry were used. Although the use of pH adjustment achieved effective improvement to membrane operation, it was 15% less effective than applying a pre-treatment of flocculation of TiO_2 slurry. Photocatalysis and flocculation pre-treatment processes before MF/UF also resulted in high (over 90%) DOC removal, surpassing those achieved with mixed TiO_2 and PAC photocatalyst.

Acknowledgements

First, I would like to thank my greatest appreciation to my principal supervisor, Professor Saravanmuthu Vigneswaran for his patience, time, guidance, encouragement, throughout my studies. I would like to thank my co supervisors Dr Jaya Kandasamy, Associate Professor Huu- Hao Ngo, and Prof Archie Johnson for their support and guidance during my PhD course. I am also very grateful to Prof. Archie Johnson the Dean of Faculty of Engineering for taking his precious time for correction of my PhD thesis.

Warm thanks to all my great friends, Laszlo, Shon, Guo, Rong, Vinh, Javeed, and Wen. The teamwork and friendships developed with these people contributed greatly to my happiness and fun times we shared.

Many thanks also to The Office of Education Affairs Australia, and Office of Civil Service Commission Thailand for support and help during my PhD degree.

Most importantly, thank you to my wife and my parents for their love, for their encouragement and support. Especially my wife, Sirilak, you always had time to listen and discuss all problems with me. And most of all thank you for your love.

Figure 7.4 DOC removal of synthetic wastewater with various flow rates (conditions; $TiO_2 = 1.5$ g/L, and PAC 0.05 g/L $Q_1 = 60, 100, 250$ mL/min, L1, L2, L3 = 8 Watts UV Lamps)	185
Figure 7.5 Photocatalytic DOC removal with 1.5 g/L TiO_2 catalyst (Figure 4.4 ($Q_1 = 10, 20, 40$ mL/min, Q_2 150 mL/min R: photo-catalytic reactor unit; L1, L2, L3 are UV lamps of 8 watts each).....	187
Figure 7.6 Photocatalytic DOC removal with 1.5 g/L TiO_2 and 0.05 g/L PAC (Figure 4.4 ($Q_1 = 10, 20, 30, 40$ mL/min, Q_2 150 mL/min R: photo-catalytic reactor unit; L1, L2, L3 are UV lamps of 8 watts each).....	189

Figure 7.7 Variation of zeta potential (ZP) with a treated suspension (1.5 g/L of TiO ₂)	190
Figure 7.8 Screen showed stepwise method increase of flux, 10 to 15 min monitoring of the TMP trendline (start at 2.09.32 pm. end at 2.25 45 pm.)	194
Figure 7.9 second screen showed stepwise method increase of flux, 10 to 15 min monitoring of the TMP trendline (start at 2.09.46 pm. end at 2.30.02 pm.)	194
Figure 7.10 Third screen showed stepwise method increase of flux, 10 to 15 min monitoring of the TMP trendline (start at 2.28.07 pm. end at 2.40.30 pm.)	195
Figure 7.11 Fourth screen showed stable TMP trend, and this value was reported as the critical flux	195
Figure 7.12 Settled turbidity versus coagulant dosage (wastewater slurry with 1.5 g/L of TiO ₂ (Feed 40 mL/min; Feed 2 10mL/min)	198
Figure 7.13 Effect of coagulant dosage on ZP and pH feed 1	199
Figure 7.14 %DOC removal with different coagulant dosage with raw synthetic waste water	199
Figure 7.15. Critical fluxes 1: raw wastewater, 2: Feed 1 pH adjusted, 3: Feed 2 pH adjusted, 4: Feed 1 flocculated, 5: Feed 2 flocculated, 6: Feed 3 (photocatalyst together with PAC)	201

LIST OF TABLES

Table 2.1 Removal of EDC and PPCP from BTSE by PAC adsorption (adapted from Snyder et al., 2006; Westerhoff et al., 2005, Shon et al., 2006)	25
Table 2.2 Removal of EDC and PPCP with full scale GAC biofilter (ng/L) (Snyder et al., 2006; Shon et al., 2006)	28
Table 2.3 Typical biofilter design parameters used in tertiary wastewater and surface water treatment (adapted from Rachwal et al., 1996)	31
Table 2.4 List of the DOC removal by filtration with biological treated sewage effluent (BTSE)	31
Table 2.5 Advanced oxidation processes used in water treatment (Shon et al., 2006) ..	33
Table 2.6 Bandgap energies from some common semiconductor materials at 0 K (Adapted from Serpone and Pelizzetti 1989 and Schiavello and Sclafani 1997, Sakthivel et al. 2000, Thiruvengkatachari et al. 2007)	37
Table 2.7 Overview of various reactor types	48
Table 2.8 Review of organic pollutants removal by AOPs hybrid system adapted from Shon et al., 2006.....	50
Table 2.9 Easily oxidized organic compounds by photocatalytic processes (adapted from Pirkanniemi and Sillanpää, 2002; Shon et al., 2006)	52
Table 3.1 Specification of Metsulfuron methyl	61
Table 3.2 Constituents of synthetic wastewater that used in experiments.....	63
Table 3.3 Characteristics of the TiO ₂ P25 Degussa photocatalytic powder used in the present experiments.....	64
Table 3.4 Characteristics of Powdered Activated Carbon (PAC) used (James Cumming & Sons Pty Ltd., Australia).....	65
Table 3.5 Physical properties of granular activated carbon GAC (Calgon Carbon Corp., USA)	66
Table 3.6 Sankyo Denki UV lamp specification.....	67
Table 4.1 pH and photocatalysis	99
Table 5.1 Variation of rate constant at different concentrations of TiO ₂	125
Table 5.2 Apparent rate constants obtained at different concentrations of TiO ₂ and at PAC concentration of 0.05 g/L	129

Table 5.3 DOC removal at different detention time (MM concentration =10 mg/L, TiO ₂ = 1.5 g/L, PAC = 0.05 g/L)	143
Table 5.4 Variation of pseudo first order rate constant obtained from Equation (9) at different withdrawal rates of 1.5 g/L TiO ₂	148
Table 5.5 Variation of pseudo first order rate constant obtained from Equation (9) at different withdrawal rate of 1.5 g/L TiO ₂ and 0.05 g/L PAC	148
Table 6.1 Equilibrium adsorption isotherm parameters.....	159
Table 6.2 Parameters used for model simulation of GAC filter	166
Table 6.3 DOC removal at different retention time (MM concentration = 10 mg/L, TiO ₂ =1.5 g/L , reactor volume 210 mL, 8 W UV light three lamps)	171
Table 6.4 DOC removal at different retention time (MM concentration =10 mg/L, TiO ₂ = 1.5 g/L, PAC = 0.05 g/L , reactor volume 210 mL, 8 watts UV light, 3 lamps and after GAC adsorption at bed depths of 5, 10, and 15 cm.	173
Table 7. 1. Characteristics of raw wastewater and TiO ₂ treated suspensions.....	191
Table 7.2. Jar test results with 1 g/L of TiO ₂ treated suspensions	197
Table A.1 Limits of detection for 50 minute extraction of selected herbicides adapted from (Boyd-Boland & Pawliszyn 1995)	213
Table A. 2 Relative factor of increase of K at humic acid concentration (C _H , in mg/L) of 0,20,100,500 mg/L; expected relative factor of increase based on the mass balance (C _{calc}) and the logarithm of the octanol – water partitioning coefficient (log K _{ow}) applied in the mass balance (Dewulf, Van Langenhove & Evaraert 1997). ..	215
Table A.3 Application of SPME/ GC to the identification of herbicides in aqueous sample (LOD; limit of detection, DI ; direct insertion, HS; head space, PDMS; polydimethylsiloxane, PA; polyacrylate, DVB; Divinylbenzene, CAR; Carboxen, CW; Carbowax, TPR; Templated resin)	217
